## OUTLINE

- The vargaprakrti equation $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=\mathrm{K}$, and Brahmagupta's bhāvanā process (c. 628 CE ).
- The cakravāla method of solution of Jayadeva (c. $10^{\text {th }}$ cent) and Bhāskara (c.1150).
- Bhāskara's examples $\mathrm{X}^{2}-61 \mathrm{Y}^{2}=1, \mathrm{X}^{2}-67 \mathrm{Y}^{2}=1$.
- Analysis of the cakravāla method by Krishnaswami Ayyangar.
- History of the so called "Pell's Equation" $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=1$.
- Solution of "Pell's equation" by expansion of $\sqrt{ } D$ into a simple continued fraction (c. $18^{\text {th }}$ cent).
- Bhāskara semi-regular continued fraction expansion of $\sqrt{ } D$
- Optimality of the cakravāla method.

## VARGA PRAKRTII

In Chapter XVIII of his Brāhmasphuta-siddhānta (c. 628 CE), Brahmagupta considers the problem of solving for integral values of X , Y , the equation

$$
\mathbf{X}^{2}-\mathbf{D} \mathbf{Y}^{2}=\mathbf{K}
$$

given a non-square integer $\mathrm{D}>0$, and an integer K .
X is called the larger root (jyestha-mūla), Y is called the smaller root (kaniṣtha-mūla), D is the prakrti, K is the kṣepa.

One motivation for this problem is that of finding rational approximations to square-root of D . If $\mathrm{X}, \mathrm{Y}$ are integers such that $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=1$, then,

$$
\left|\sqrt{D}-\frac{x}{y}\right| \leq \frac{1}{2 x y}
$$

The Śulva-sūtra approximation (prior to 800 BCE):
$\sqrt{ } 2 \approx 1+1 / 3+1 / 3.4-1 / 3.4 .34=577 / 408 \quad\left[(577)^{2}-2(408)^{2}=1\right]$

## BRAHMAGUPTA'S BHĀVANĀ

मूलं द्विधेष्टवर्गाद् गुणकगुणादिष्टयुतविहीनाच्च।
आद्यवधो गुणकगुणः सहान्त्यघातेन कृतमन्त्यम्॥
वज्रवधैक्यं प्रथमं प्रक्षेपःक्षेपवधतुल्यः।
प्रक्षेपशोधकह्टते मूले प्रक्षेपके रूपे॥

If $\quad \mathrm{X}_{1}{ }^{2}-\mathrm{D} \mathrm{Y}_{1}{ }^{2}=\mathrm{K}_{1}$ and $\mathrm{X}_{2}{ }^{2}-\mathrm{D} \mathrm{Y}_{2}{ }^{2}=\mathrm{K}_{2}$ then
$\left(X_{1} \mathbf{X}_{2} \pm \mathbf{D} Y_{1} \mathbf{Y}_{2}\right)^{2}-\mathbf{D}\left(\mathbf{X}_{1} \mathbf{Y}_{2} \pm \mathbf{X}_{2} \mathbf{Y}_{1}\right)^{\mathbf{2}}=K_{1} K_{2}$
In particular given $X^{2}-D Y^{2}=K$, we get the rational solution

$$
\left[\left(\mathrm{X}^{2}+\mathrm{D} \mathrm{Y} \mathrm{Y}^{2}\right) / \mathrm{K}\right]^{2}-\mathrm{D}[(2 \mathrm{XY}) / \mathrm{K}]^{2}=1
$$

Also, if one solution of the Equation $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=1$ is found, an infinite number of solutions can be found, via

$$
(\mathrm{X}, \mathrm{Y}) \rightarrow\left(\mathrm{X}^{2}+\mathrm{D} \mathrm{Y}^{2}, 2 \mathrm{XY}\right)
$$

## USE OF BHĀVANĀ WHEN $K=-1, \pm 2, \pm 4$

The bhāvana principle can be use to obtain a solution of the equation

$$
X^{2}-\mathrm{D} Y^{2}=1,
$$

if we have a solution of the equation

$$
\begin{aligned}
& X_{1}^{2}-\mathrm{D} Y_{1}^{2}=\mathrm{K}, \text { for } \mathrm{K}=-1, \pm 2, \pm 4 . \\
& K=-1: x=x_{1}^{2}+D y_{1}^{2}, y=2 x_{1} y_{1} . \\
& K= \pm 2: x=\frac{\left(x_{1}^{2}+D y_{1}^{2}\right)}{2}, y=x_{1} y_{1} . \\
& K=-4: x=\left(x_{1}^{2}+2\right)\left[\frac{1}{2}\left(x_{1}^{2}+1\right)\left(x_{1}^{2}+3\right)-1\right] \\
& y=\frac{x_{1} y_{1}\left(x_{1}^{2}+1\right)\left(x_{1}^{2}+3\right)}{2} . \\
& K-4: x-\frac{\left(x_{1}^{2}-2\right)}{2}, y-\frac{x_{1} y_{1}}{2}, \text { if } x_{1} \text { is even, } \\
& x=\frac{x_{1}\left(x_{1}^{2}-3\right)}{2}, y=\frac{y_{1}\left(x_{1}^{2}-1\right)}{2}, \text { if } x_{1} \text { is odd. }
\end{aligned}
$$

## BRAHMAGUPTA'S EXAMPLES

राशिकलाशेषकृतिं द्विनवतिगुणितां ग्यशीतिगुणितां वा।
सैकां ज्ञदिने वर्गं कुर्वन्नावत्सराद्नणकः॥
To solve, $\mathbf{X}^{\mathbf{2}}-\mathbf{D} \mathbf{Y}^{\mathbf{2}}=\mathbf{1}$, for $\mathbf{D}=\mathbf{9 2}, \mathbf{8 3}$ :

$$
10^{2}-92.1^{2}=8
$$

Doing the bhāvana of the above with itself,

$$
192^{2}-92.20^{2}=64 \quad\left[10^{2}+92.1^{2}=192 \text { and } 2.10 .1=20\right]
$$

Dividing both sides by 64 ,

$$
24^{2}-92 \cdot(5 / 2)^{2}=1
$$

Doing the bhāvan $\bar{a}$ of the above with itself,

$$
\mathbf{1 1 5 1}^{\mathbf{2}}-\mathbf{9 2 . 1 2 0}{ }^{2}=\mathbf{1} \quad\left[24^{2}+92 .(5 / 2)^{2}=1151 \text { and } 2.24 .(5 / 2)=120\right]
$$

Similarly,

$$
9^{2}-83.1^{2}=-2
$$

Doing the bhāvana of the above with itself, $164^{2}-83.18^{2}=4$ and hence, $\mathbf{8 2}^{\mathbf{2}}-\mathbf{8 3 . 9} \mathbf{9}^{\mathbf{2}}=\mathbf{1}$.

## CAKRAVĀLA: THE CYCLIC METHOD

The first known description of the Cakravāla or the Cyclic Method occurs in a work of Udayadivākara (c.1073), who cites the verses of Ācārya Jayadeva.

In his Bī̀jagaṇita, Bhāskarācārya (c.1150) has given the following description of the cakravāla method:

ह्रस्वज्येष्ठपदक्षेपान् भाज्यप्रक्षेपभाजकान्। कृत्वा कल्प्यो गुणस्तत्र तथा प्रकृतितश्व्युते॥ गुणवर्गे प्रकृत्योनेऽथवाल्पं शेषकं यथा। तत्तु क्षेपह्तं क्षेपो व्यस्तः प्रकृतितश्व्युते॥ गुणलब्धिः पदं ह्नस्वं ततो ज्येष्टमतोऽसकृत्। त्यक्त्वा पूर्वपदक्षेपांश्चक्रवालमिदं जगुः॥ चतुर्द्वेकयुतावेवमभिन्ने भवतः पदे। चतुर्द्विक्षेपमूलाभ्यां रूपक्षेपार्थभावना॥

## THE CAKRAVĀLA METHOD

Given $\mathrm{X}_{\mathrm{i}}, \mathrm{Y}_{\mathrm{i}}, \mathrm{K}_{\mathrm{i}}$ such that $\mathrm{X}_{\mathrm{i}}{ }^{2}-\mathrm{D} \mathrm{Y}_{\mathrm{i}}{ }^{2}=\mathrm{K}_{\mathrm{i}}$
First find $\mathrm{P}_{\mathrm{i}+1}$ as follows:
(I) Use kutt!aka process to solve (the linear indeterminate equation)

$$
\left(\mathbf{Y}_{\mathbf{i}} \mathbf{P}_{\mathbf{i}+1}+\mathbf{X}_{\mathbf{i}}\right) /\left|\mathbf{K}_{\mathrm{i}}\right|=\mathbf{Y}_{\mathbf{i}+1}
$$

for integral $\mathbf{P}_{\mathrm{i}+1}, \mathbf{Y}_{\mathrm{i}+1}$
(II) Of the solutions of the above, choose $P_{i+1}>0$, such that $l\left(\mathbf{P}_{\mathrm{i}+1}{ }^{2}-\mathbf{D}\right) \mid$ has the least value
Then set

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{i}+1}=\left(\mathrm{P}_{\mathrm{i}+1}^{2}-\mathrm{D}\right) / \mathrm{K}_{\mathrm{i}} \\
& \mathrm{Y}_{\mathrm{i}+1}=\left(\mathrm{Y}_{\mathrm{i}} \mathrm{P}_{\mathrm{i}+1}+\mathrm{X}_{\mathrm{i}}\right) /\left|\mathrm{K}_{\mathrm{i}}\right| \\
& \mathrm{X}_{\mathrm{i}+1}=\left(\mathrm{X}_{\mathrm{i}} \mathrm{P}_{\mathrm{i}+1}+\mathrm{D} \mathrm{Y}_{\mathrm{i}}\right) / / \mathrm{K}_{\mathrm{i}} \mid
\end{aligned}
$$

These satisfy $\mathrm{X}_{\mathrm{i}+1}{ }^{2}-\mathrm{D} \mathrm{Y}_{\mathrm{i}+1}{ }^{2}=\mathrm{K}_{\mathrm{i}+1}$
Iterate the process till $\mathrm{K}_{\mathrm{i}+1}= \pm 1, \pm 2$ or $\pm 4$, and then solve the equation using bhāvanā if necessary.

## THE CAKRAVĀLA METHOD

In 1930, Krishnaswami Ayyangar showed that the cakravāla procedure always leads to a solution of the equation $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=1$.

He also showed that condition (I) is equivalent to the simpler condition
(I') $\mathbf{P}_{\mathbf{i}}+\mathbf{P}_{\mathrm{i}+1}$ is divisible by $\mathrm{K}_{\mathrm{i}}$
Thus, we shall now use the cakravāla algorithm in the following form:
To solve $\mathbf{X}^{\mathbf{2}}-\mathbf{D} \mathbf{Y}^{\mathbf{2}}=\mathbf{1}$ :
Set $\mathrm{X}_{0}=1, \mathrm{Y}_{0}=0, \mathrm{~K}_{0}=1$ and $\mathrm{P}_{0}=0$.
Given $X_{i}, Y_{i}, K_{i}$ such that $X_{i}{ }^{2}-D Y_{i}^{2}=K_{i}$
First find $\quad \mathrm{P}_{\mathrm{i}+1}>0$ so as to satisfy:
(I') $\mathbf{P}_{\mathrm{i}}+\mathbf{P}_{\mathrm{i}+1}$ is divisible by $\mathrm{K}_{\mathrm{i}}$
(II) $\mid \mathbf{P}_{\mathrm{i}+1}{ }^{2}$-D $\mid$ is minimum.

## THE CAKRAVĀLA METHOD

Then set

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{i}+1}=\left(\mathrm{P}_{\mathrm{i}+1}^{2}-\mathrm{D}\right) / \mathrm{K}_{\mathrm{i}} \\
& \mathrm{Y}_{\mathrm{i}+1}=\left(\mathrm{Y}_{\mathrm{i}} \mathrm{P}_{\mathrm{i}+1}+\mathrm{X}_{\mathrm{i}}\right) /\left|\mathrm{K}_{\mathrm{i}}\right|=a_{i} \mathrm{Y}_{\mathrm{i}}+\varepsilon_{\mathrm{i}} \mathrm{Y}_{\mathrm{i}-1} \\
& \mathrm{X}_{\mathrm{i}+1}=\left(\mathrm{X}_{\mathrm{i}} \mathrm{P}_{\mathrm{i}+1}+\mathrm{DY} \mathrm{Y}_{\mathrm{i}}\right) /\left|\mathrm{K}_{\mathrm{i}}\right|=\mathrm{P}_{\mathrm{i}+1} \mathrm{Y}_{\mathrm{i}+1}-\operatorname{sign}\left(\mathrm{K}_{\mathrm{i}}\right) \mathrm{K}_{\mathrm{i}+1} \mathrm{Y}_{\mathrm{i}}=a_{i} \mathrm{X}_{\mathrm{i}}+\varepsilon_{\mathrm{i}} \mathrm{X}_{\mathrm{i}-1}
\end{aligned}
$$

These satisfy $X_{i+1}{ }^{2}-D Y_{i+1}{ }^{2}=K_{i+1}$
Iterate till $\mathrm{K}_{\mathrm{i}+1}= \pm 1, \pm 2$ or $\pm 4$, and then use bhāvan $\bar{a}$ if necessary.
Note: We also need $a_{i}=\left(\mathbf{P}_{\mathbf{i}}+\mathbf{P}_{\mathbf{i}+1}\right) /\left|\mathbf{K}_{\mathrm{i}}\right|$ and $\varepsilon_{\mathrm{i}}=\left(\mathbf{D}-\mathbf{P}_{\mathbf{i}}{ }^{2}\right) /\left|\mathbf{D}-\mathbf{P}_{\mathbf{i}}{ }^{2}\right|$ with $\varepsilon_{0}=1$.

## BHĀSKARA'S EXAMPLES

का सप्तषष्टिगुणिता कृतिरेकयुक्ता का चैकषष्टिनिहता च सखे सरूपा। स्यान्मूलदा यदि कृतिप्रकृतिर्नितान्तं त्वच्चेतसि प्रवद तात तता लतावत्॥

द्वितीयोदाहरणे न्यास:-
प्र ६१ क १ ज्ये 5 क्षे अ।
कुट्टार्थं न्यास: भा 9 हा ₹ क्षे $=1$
हरतष्टे धनक्षेपे इति लनिधगुणो ३े। इष्टाहतेति द्वाभ्यामुत्थाव्य जातो लन्धि गुणो जै। गुणवर्गे ४९। प्रकृतेः शोधिते १२. व्य₹त इति ॠणम् १२ं इदं क्षेपह्तूतं जात: क्षेपः ४ं। अतः प्राग्वज्जाते चतु: क्षेपमूले क $x$ ज्ये ३९।

इष्टवर्गहृतः क्षेप स्यादित्युपपन्नख्प शुद्यिमूलयोर्भावनार्थं न्यास:--

$$
\begin{aligned}
& \text { क } \frac{x}{२} \text { ज्ये } \frac{\beta ?}{२} \text { क्षे } 9^{\circ} \\
& \text { क } \frac{x}{२} \text { ब्ये } \frac{3 \varrho}{२} \text { क्षे } 9^{\circ}
\end{aligned}
$$

## BHĀSKARA'S EXAMPLE: $X^{2}-61 Y^{2}=1$

| $\mathbf{I}$ | $\mathbf{P}_{\mathbf{i}}$ | $\mathbf{K}_{\mathbf{i}}$ | $\mathbf{a}_{\mathbf{i}}$ | $\boldsymbol{\varepsilon}_{\mathbf{i}}$ | $\mathbf{X}_{\mathbf{i}}$ | $\mathbf{Y}_{\mathbf{i}}$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0 | 1 | 8 | 1 |  | 1 |
| 1 | 8 | 3 | 5 | -1 | 8 | 0 |
| 2 | 7 | -4 | 4 | 1 | 39 | 1 |
| 3 | 9 | -5 | 3 | -1 | 164 | 5 |

To find $P_{1}: 0+7,0+8,0+9 \ldots$ divisible by $1.8^{2}$ closest to $61 . P_{1}=8, K_{1}=3$
To find $P_{2}: 8+4,8+7,8+10 \ldots$ divisible by $3.7^{2}$ closest to $61 . P_{2}=7, K_{2}=-4$ After the second step, we have: $39^{2}-61.5^{2}=-4$

Now, since have reached $\mathrm{K}=-4$, we can use bhāvanā principle to obtain

$$
\begin{aligned}
& X=\left(39^{2}+2\right)\left[(1 / 2)\left(39^{2}+1\right)\left(39^{2}+3\right)-1\right]=\mathbf{1 , 7 6 6 , 3 1 9 , 0 4 9} \\
& Y=(1 / 2)(39.5)\left(39^{2}+1\right)\left(39^{2}+3\right)=\mathbf{2 2 6 , 1 5 3 , 9 8 0} \\
& 1766319049^{2}-61.226153980^{2}=1
\end{aligned}
$$

## BHĀSKARA'S EXAMPLE: $X^{2}-61 Y^{2}=1$

| $\mathbf{I}$ | $\mathbf{P}_{\mathbf{i}}$ | $\mathbf{K}_{\mathbf{i}}$ | $\mathbf{a}_{\mathbf{i}}$ | $\boldsymbol{\varepsilon}_{\mathbf{i}}$ | $\mathbf{X}_{\mathbf{i}}$ | $\mathbf{Y}_{\mathbf{i}}$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0 | 1 | 8 | 1 | 1 | 0 |
| 1 | 8 | 3 | 5 | -1 | 8 | 1 |
| 2 | 7 | -4 | 4 | 1 | 39 | 5 |
| 3 | 9 | -5 | 3 | -1 | 164 | 21 |
| 4 | 6 | 5 | 3 | 1 | 453 | 58 |
| 5 | 9 | 4 | 4 | -1 | 1,523 | 195 |
| 6 | 7 | -3 | 5 | 1 | 5,639 | 722 |
| 7 | 8 | -1 | 16 | -1 | 29,718 | 3,805 |
| 8 | 8 | -3 | 5 | -1 | 469,849 | 60,158 |
| 9 | 7 | 4 | 4 | 1 | $2,319,527$ | 296,985 |
| 10 | 9 | 5 | 3 | -1 | $9,747,957$ | $1,248,098$ |
| 11 | 6 | -5 | 3 | 1 | $26,924,344$ | $3,447,309$ |
| 12 | 9 | -4 | 4 | -1 | $90,520,989$ | $11,590,025$ |
| 13 | 7 | 3 | 5 | 1 | $335,159,612$ | $42,912,791$ |
| 14 | 8 | 1 | 16 | -1 | $\mathbf{1 , 7 6 6 , 3 1 9 , 0 4 9}$ | $\mathbf{2 2 6 , 1 5 3 , 9 8 0}$ |

## BHASKARA'S EXAMPLE: $\mathrm{X}^{2}-67 \mathrm{Y}^{2}=1$

| $\mathbf{I}$ | $\mathbf{P}_{\mathbf{i}}$ | $\mathbf{K}_{\mathbf{i}}$ | $\mathbf{a}_{\mathbf{i}}$ | $\boldsymbol{\varepsilon}_{\mathbf{i}}$ | $\mathbf{X}_{\mathbf{i}}$ | $\mathbf{Y}_{\mathbf{i}}$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0 | 1 | 8 | 1 | 1 | 0 |
| 1 | 8 | -3 | 5 | 1 | 8 | 1 |
| 2 | 7 | 6 | 2 | 1 | 41 | 5 |
| 3 | 5 | -7 | 2 | 1 | 90 | 11 |
| 4 | 9 | -2 | 9 | -1 | 221 | 27 |
| 5 | 9 | -7 | 2 | -1 | 1,899 | 232 |
| 6 | 5 | 6 | 2 | 1 | 3,577 | 437 |
| 7 | 7 | -3 | 5 | 1 | 9,053 | 1,106 |
| 8 | 8 | 1 | 16 | 1 | $\mathbf{4 8 , 8 4 2}$ | $\mathbf{5 , 9 6 7}$ |

To find $P_{1}: 0+7,0+8,0+9 \ldots$ divisible by $1.8^{2}$ closest to $67 . P_{1}=8, K_{1}=-3$ To find $\mathrm{P}_{2}: 8+4,8+7,8+10 \ldots$ divisible by $3.7^{2}$ closest to $67 . \mathrm{P}_{2}=7, \mathrm{~K}_{2}=6$ To find $P_{3}: 7+5,7+11,7+17 \ldots$ divisible by $6.5^{2}$ closest to $67 P_{3}=5, K_{3}=-7$ To find $P_{4}: 5+2,5+9,5+16 \ldots$ divisible by $7.9^{2}$ closest to $67 \mathrm{P}_{4}=9, \mathrm{~K}_{4}=-2$ Now, since have reached $\mathrm{K}=-2$, we can do bhāvana to find the solution:

$$
48842^{2}-2.5967^{2}=1 \quad\left[48842=\left(221^{2}+67.27^{2}\right) / 2 \text { and } 5967=221.27\right]
$$

## MODERN SCHOLARSHIP ON CAKRAVĀLA

It is not known whether Bachet, Fermat or their successors in $17^{\text {th }}$ and $18^{\text {th }}$ century were aware of the Indian work on indeterminate equations.

The Būjaganita of Bhāskara, was translated in to English from the Persian Translation of Ata Allah Rushdi (1634) by Edward Strachey with Notes by Samuel Davis (London, 1813). In 1817, Henry Thomas Colbrooke published Algebra with Arithmetic and Mensuration from the Sanskrit of Brahmagupta and Bhascara (London, 1817), which included a tranlsation of Gaṇitädhyāya and Kutṭakādhyāya of Brāhmasphuṭa-siddhānta, and the Lūlāvatī and Būjagaṇita of Bhāskara.

The true nature of cakravāla method was not understood for long. In the second edition (1910) of his work on Diophantus, Edward Heath notes:

On the Indian method Hankel [1874] says, 'It is above all praise; it is certainly the finest thing which was achieved in theory of numbers before Lagrange'; and although this may seem an exaggeration when we think of the extraordinary achievements of Fermat, it is true that the Indian method is, remarkably though, the same as that which was rediscovered and expounded by Lagrange in 1768.

## ANALYSIS OF CAKRAVĀLA PROCESS

In 1930, A. A. Krishnaswami Ayyangar (1892-1953) presented a detailed analysis of the cakravāla process. He explained how it is different from and more optimal than the Euler-Lagrange process based on the simple continued fraction expansion of VD . He also showed that the cakravāla process always leads to a solution of the vargaprakrti equation with $\mathrm{K}=1$.

Let us consider the equations

$$
\begin{aligned}
& \mathrm{X}_{\mathrm{i}}{ }^{2}-\mathrm{D} \mathrm{Y} \mathrm{Y}_{\mathrm{i}}{ }^{2}=\mathrm{K}_{\mathrm{i}} \\
& \mathrm{P}_{\mathrm{i}+1}{ }^{2}-\mathrm{D} \cdot 1^{2}=\mathrm{P}_{\mathrm{i}+1}{ }^{2}-\mathrm{D}
\end{aligned}
$$

By doing bhāvana $\bar{a}$ of these, and dividing by $\mathrm{K}_{\mathrm{i}}{ }^{2}$, we get

$$
\left[\left(\mathbf{X}_{\mathbf{i}} \mathbf{P}_{\mathbf{i}+1}+\mathbf{D} \mathbf{Y}_{\mathbf{i}}\right) /\left|\mathbf{K}_{\mathrm{i}}\right|\right]^{2}-\mathbf{D}\left[\left(\mathbf{Y}_{\mathbf{i}} \mathbf{P}_{\mathbf{i}+1}+\mathbf{X}_{\mathbf{i}}\right) /\left|\mathbf{K}_{\mathrm{i}}\right|\right]^{2}=\left(\mathbf{P}_{\mathbf{i}+1}{ }^{2}-\mathbf{D}\right) / \mathbf{K}_{\mathbf{i}}
$$

If we assume that $X_{i}, Y_{i}$ and $K_{i}$ are mutually prime, and if we choose $P_{i+1}$ such that $Y_{i+1}=\left[\left(Y_{i} P_{i+1}+X_{i}\right) / I K_{i} \mid\right]$ is an integer, then it can be shown that $X_{i+1}=\left[\left(X_{i} \mathrm{P}_{\mathrm{i}+1}+\mathrm{DY} \mathrm{Y}_{\mathrm{i}}\right) / \mathrm{K}_{\mathrm{i}}\right]$ and $\mathrm{K}_{\mathrm{i}+1}=\left(\mathrm{P}_{\mathrm{i}+1}{ }^{2}-\mathrm{D}\right) / \mathrm{K}_{\mathrm{i}}$ are both integers.

## ANALYSIS OF CAKRAVĀLA PROCESS

Further, we have

$$
\begin{aligned}
\mathrm{X}_{\mathrm{i}+2} & =\left[\left(\mathrm{X}_{\mathrm{i}+1} \mathrm{P}_{\mathrm{i}+2}+\mathrm{DY} \mathrm{Y}_{\mathrm{i}+1}\right) /\left|\mathrm{K}_{\mathrm{i}+1}\right|\right] \\
& =\mathrm{X}_{\mathrm{i}+1}\left[\left(\mathrm{P}_{\mathrm{i}+2}+\mathrm{P}_{\mathrm{i}+1}\right) /\left|\mathrm{K}_{\mathrm{i}+1}\right|\right]+\mathrm{X}_{\mathrm{i}}\left(\mathrm{D}-\mathrm{P}_{\mathrm{i}+1}^{2}\right) /\left|\mathrm{K}_{\mathrm{i}}\right|\left|\mathrm{K}_{\mathrm{i}+1}\right| \\
& =\mathrm{a}_{\mathrm{i}+1} \mathrm{X}_{\mathrm{i}+1}+\varepsilon_{\mathrm{i}+1} \mathrm{X}_{\mathrm{i}}
\end{aligned}
$$

and similarly for $\mathrm{Y}_{\mathrm{i}+2}$.
Therefore, instead of using the kuttaka process for finding $\mathrm{P}_{\mathrm{i}+2}$, we can use the condition that

$$
\mathbf{P}_{i+1}+\mathbf{P}_{i+2} \text { is divisible by } K_{i+1} .
$$

## ANALYSIS OF CAKRAVĀLA PROCESS

Krishnaswami Ayyangar, then proceeds to an analysis of the quadratic forms $\left(K_{i}, P_{i+1}, K_{i+1}\right)$ which satisfy $P_{i+1}{ }^{2}-K_{i} K_{i+1}=D$.

Notation: $(A, B, C)$ stands for the quadratic form $\mathrm{A} x^{2}+2 \mathrm{~B} x y+\mathrm{C} y^{2}$
The form $\left(\mathrm{K}_{\mathrm{i}+1}, \mathrm{P}_{\mathrm{i}+2}, \mathrm{~K}_{\mathrm{i}+2}\right)$, which is obtained from $\left(\mathrm{K}_{\mathrm{i}}, \mathrm{P}_{\mathrm{i}+1}, \mathrm{~K}_{\mathrm{i}+1}\right)$ by the cakravāla process, is called the successor of the latter.

Ayyangar defines a quadratic form (A, B, C) to be a Bhāskara form if

$$
\mathrm{A}^{2}+\left(\mathrm{C}^{2} / 4\right)<\mathrm{D} \text { and } \mathrm{C}^{2}+\left(\mathrm{A}^{2} / 4\right)<\mathrm{D}
$$

He shows that the successor of a Bhāskara form is also a Bhāskara form and that two different Bhāskara forms cannot have the same successor.

## ANALYSIS OF CAKRAVĀLA PROCESS

Krishnaswami Ayyangar considers the general case when we start the cakravāla process with an arbitrary initial solution

$$
\mathrm{X}_{0}{ }^{2}-\mathrm{D} \mathrm{Y}_{0}{ }^{2}=\mathrm{K}_{0}
$$

He shows that if $\left|K_{0}\right|>\sqrt{ }$ D, then the absolute values of the successive $K_{i}$ decrease monotonically, till say $K_{m}$, after which we have

$$
\left|\mathbf{K}_{\mathbf{i}}\right|<\sqrt{ } \mathbf{D} \text { for } i>m .
$$

He also shows that

$$
\left|\mathbf{P}_{\mathbf{i}}\right|<\mathbf{2} \sqrt{ } \mathbf{D} \text { for } i>m .
$$

Since $\left|\mathrm{K}_{\mathrm{i}}\right|$ cannot go on decreasing, for some $r>m$ we have $\left|\mathrm{K}_{\mathrm{r}+1}\right|>\left|\mathrm{K}_{\mathrm{r}}\right|$. It can then be shown that $\left(\mathrm{K}_{\mathrm{r}}, \mathrm{P}_{\mathrm{r}+1}, \mathrm{~K}_{\mathrm{r}+1}\right)$ and all the succeeding forms will be Bhāskara forms.

## ANALYSIS OF CAKRAVĀLA PROCESS

If we start with the initial solution $\mathrm{X}_{0}=1, \mathrm{Y}_{0}=0$ and $\mathrm{K}_{0}=1$, then we see that cakravāla process leads to $\mathrm{P}_{1}=\mathrm{X}_{1}=d$, where $d>\mathrm{o}$ is the integer such that $\mathrm{d}^{2}$ is the square nearest to $D$. Also $\mathrm{Y}_{0}=1$ and $K_{1}=d^{2}$-D.

Ayyangar shows that $\left(\mathrm{K}_{0}, \mathrm{P}_{1}, \mathrm{~K}_{1}\right) \equiv\left(1, \mathrm{~d}, \mathrm{~d}^{2}-\mathrm{D}\right)$ is a Bhāskara form. So is the form $\left(d^{2}-D, d, 1\right)$ which is equivalent to it.

Since the values of $\mathrm{K}_{\mathrm{i}}, \mathrm{P}_{\mathrm{i}}$ are bounded, the Bhāskara forms will have to repeat in a cycle and the first member of the cycle is the same as the first Bhāskara form which is obtained in the course of cakravāla.

Finally, Ayyangar shows that two different cycles of Bhāskara forms are non-equivalent, and that all equivalent Bhāskara forms belong to the same cycle.

## ANALYSIS OF CAKRAVĀLA PROCESS

Ayyangar sets up an association between a Bhāskara form ( $\mathrm{K}_{\mathrm{i}}, \mathrm{P}_{\mathrm{i}+1}, \mathrm{~K}_{\mathrm{i}+1}$ ) an equivalent Gauss form $\left(K_{i}^{\prime}, P_{i+1}{ }^{\prime}, K_{i+1}\right)$, which satisfies

$$
\sqrt{ } \mathrm{D}-\mathrm{P}_{\mathrm{i}+1^{\prime}}<\left|\mathrm{K}_{\mathrm{i}}^{\prime}\right|<\sqrt{ } \mathrm{D}+\mathrm{P}_{\mathrm{i}+1^{\prime}} .
$$

If $P_{i+1}<\sqrt{ } \mathrm{D}$, then $\left(\mathrm{K}_{\mathrm{i}}^{\prime}, \mathrm{P}_{\mathrm{i}+1}{ }^{\prime}, \mathrm{K}_{\mathrm{i}+1}{ }^{\prime}\right) \equiv\left(\mathrm{K}_{\mathrm{i}}, \mathrm{P}_{\mathrm{i}+1}, \mathrm{~K}_{\mathrm{i}+1}\right)$
If $P_{i+1}>\sqrt{ } D$, then $K_{i}^{\prime}=K_{i}, P_{i+1}^{\prime}=P_{i+1}-\left|K_{i}\right|$ and $K_{i+1}^{\prime}=2 P_{i+1}-\left|K_{i}\right|-\left|K_{i+1}\right|$
In this way a Bhāskara cycle can be converted to a unique Gauss cycle and vice versa, from which the above results follow.

Thus, whatever initial solution we may start with, the cakravāla process takes us to a cycle of equivalent Bhāskara forms and since the Bhāskara form ( $\mathrm{d}^{2}-\mathrm{D}, \mathrm{d}, 1$ ) is in this equivalence class, the cakravāla process leads to a solution corresponding to $\mathrm{K}=1$.

## FERMAT'S CHALLENGE TO BRITISH MATHEMATICIANS (1657)

In February 1657, Pierre de Fermat (1601-1665) wrote to Bernard Frenicle de Bessy asking him for a general rule "for finding, when any number not a square is given, squares which, when they are respectively multiplied by the given number and unity added to the product, give squares." If Frenicle is unable to give a general solution, Fermat said, can he at least give the smallest values of x and y which will satisfy the equations $\mathbf{6 1} \boldsymbol{x}^{2}+\mathbf{1}=\boldsymbol{y}^{2}$ and $109 x^{2}+1=y^{2}$.

At the same time Fermat issued a general challenge, addressed to the mathematicians in northern France, Belgium and England, where he says:
"There is hardly anyone who propounds purely arithmetical questions, hardly anyone who understands them. Is this due to the fact that up to now arithmetic has been treated geometrically rather than arithmetically? This has indeed generally been the case both in ancient and modern works; even Diophantus is an instance. For, although he was freed himself from geometry a little more than others in that he confines his analysis to the consideration of rational numbers, yet even there geometry is not absent...

## FERMAT'S CHALLENGE TO BRITISH MATHEMATICIANS (1657)

"Now, arithmetic has so to speak, a special domain of its own, the theory of integral numbers. This was only lightly touched upon by Euclid in his Elements, and was not sufficiently studied by those who followed him...

To arithmeticians, therefore by way of lighting up the road to be followed, I propose the following theorem to be proved or problem to be solved. If they succeed in discovering the proof or solution, they will admit that questions of this kind are not inferior to the more celebrated questions in geometry in respect of beauty, difficulty or method of proof.

Given any number whatever which is not a square, there are also given infinite number of squares such that, if the square is multiplied into the given number and unity is added to the product, the result is a square....

Eg. Let it be required to find a square such that, if the product of the square and the number 149 , or 109 , or 433 etc. be increased by 1 , the result is a square."

## BROUNKER-WALLIS SOLUTION

Fermat's Challenge was addressed to William Brouncker (1620-1684) and John Wallis (1616-1703). Brouncker's first response merely contained rational solutions and this led to Fermat complaining (in a letter to the interlocutor Kenelm Digby in August 1657) that they were no solutions at all to the problem that he had posed.

Brouncker then worked out his method of integral solutions which he sent to Wallis to be communicated to Fermat. Wallis describes the method of solution in two letters dated December 17, 1657 and January 30, 1658. Later in 1658, Wallis published the entire correspondence as Commercium Epistolicum. He also outlined the method in his Algebra published in English in 1685 and in Latin in 1693.

We do not know what method Fermat had for the solution of the problem he posed. Of course he communicated to the English mathematicians that he "willingly and joyfully acknowledges" the validity of their solutions. He however wrote to Huygens in 1659 that the English had failed to give "a general proof", which according to him could only be obtained by the "method of descent".

## EULER-LAGRANGE METHOD OF SOLUTION

In a letter to Goldbach written on August 10, 1730, Leonhard Euler (17071787) mentions the equation $\mathrm{X}^{2}-8 \mathrm{Y}^{2}=1$ as a special case of "Pell's Equation". He notes that "such problems have been agitated between Wallis and Fermat... and the Englishman Pell devised for them a peculiar method described in Wallis's works."

Citing the above André Weil notes:
> "Pell's name occurs frequently in Wallis's Algebra, but never in connection with the equation $\mathrm{X}^{2}-\mathrm{N}^{2}=1$ to which his name, because of Euler's mistaken attribution, has remained attached; since its traditional designation as 'Pell's equation' is unambiguous and convenient, we will go on using it even though it is historically wrong."

In a paper "De solution problematum Diophanterum per numerous integros" written in 1730, Euler describes Wallis method. He also shows that from one solution of "Pell's equation" an infinite number of solutions can be found and also remarks that they give good approximations to square-roots.

## EULER-LAGRANGE METHOD OF SOLUTION

In his letters to Goldbach in 1753 and 1755 Euler speaks of certain improvements he had made in the "Pellian method".

In a paper, read in 1759 but published in 1765 (1767), entitled "De Usu novi algoritmi in problemate Pelliano solvendo" Euler describes the method of solving $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=1$ by the simple continued fraction expansion of $\sqrt{ }$ D. He gives a table of cycles (of partial quotients) for all non-square integers from 2 to 120 and also notes their various properties.

In a paper which was published earlier in 1762-3 (1764) Euler proves the bhāvanā principle and called it "Theorema Elegantissimum".

Euler also wrote a paper in 1773 (published in 1783) on "New Aids" for solving the Pell's equation, where he describes how the equation can be solved if solution is known for $\mathrm{K}=-1,2,-2,4$.

By then, in a set of three papers presented to the Berlin Academy in 1768, 1769 and 1770, Joseph Louis Lagrange (1736-1813) had already worked out the complete theory of continued fractions and their applications to Pell's equation along with all the necessary proofs.

## RELATION WITH CONTINUED FRACTION EXPANSION

A simple continued fraction is of the form $\left(a_{\mathrm{i}}\right.$ are positive integers for $\left.i>0\right)$

$$
a_{0}+\frac{1}{a_{1}+\frac{1}{a_{2}+\frac{1}{a_{3}+}}}
$$

This is denoted by $\left[a_{0}, a_{1}, a_{2}, a_{3}, \ldots\right]$ or by

$$
a_{0}+\frac{1}{a_{1}}+\frac{1}{a_{2}}+\cdots
$$

Given any real number $\alpha$, to get the continued fraction expansion, take $a_{0}=[\alpha]$ the integral part of $\alpha$.

Let $\alpha_{1}=1 /(\alpha-[\alpha])$. Then we take $a_{1}=\left[\alpha_{1}\right]$
Let $\alpha_{2}=1 /\left(\alpha_{1}-\left[\alpha_{1}\right]\right)$. Then we take $a_{2}=\left[\alpha_{2}\right]$, and so on.
$a_{0}, a_{1}, a_{2}, .$. are called partial quotients; $\alpha_{1}, \alpha_{2}, \ldots$ are the complete quotients.

## RELATION WITH CONTINUED FRACTION EXPANSION

The $k$-th convergent of the continued fraction $\left[a_{0}, a_{1}, a_{2}, a_{3}, \ldots\right]$ is given by

$$
\mathrm{A}_{\mathrm{k}} / \mathrm{B}_{\mathrm{k}}=\left[a_{0}, a_{1}, a_{2}, a_{3}, \ldots, a_{\mathrm{k}}\right]
$$

$A_{k}, B_{k}$ satisfy the recurrence relations:

$$
\begin{aligned}
& \mathrm{A}_{0}=a_{0}, \mathrm{~A}_{1}=a_{1} a_{0}+1, \\
& \mathrm{~A}_{\mathrm{k}}=a_{\mathrm{k}} \mathrm{~A}_{\mathrm{k}-1}+\mathrm{A}_{\mathrm{k}-2} \text { for } k \geq 2 \\
& \mathrm{~B}_{0}=1, \mathrm{~B}_{1}=a_{1}, \\
& \mathrm{~B}_{\mathrm{k}}=a_{\mathrm{k}} \mathrm{~B}_{\mathrm{k}-1}+\mathrm{B}_{\mathrm{k}-2} \text { for } k \geq 2
\end{aligned}
$$

The convergents also satisfy

$$
A_{j} B_{j-1}-A_{j-1} B_{j}=(-1)^{j-1}
$$

## RELATION WITH CONTINUED FRACTION EXPANSION

## Example

$$
149 / 17=[8,1,3,4]
$$

The convergents are

$$
\mathrm{A}_{0} / \mathrm{B}_{0}=8 / 1, \mathrm{~A}_{1} / \mathrm{B}_{1}=9 / 1, \mathrm{~A}_{2} / \mathrm{B}_{2}=35 / 4, \mathrm{~A}_{3} / \mathrm{B}_{3}=149 / 17
$$

We have

$$
\mathrm{A}_{3} \mathrm{~B}_{2}-\mathrm{A}_{2} \mathrm{~B}_{3}=149.4-35.17=1
$$

This is very similar to the kuttaka method for solving $149 x-17 y=1$.
Note: The simple continued fraction expansion of a real number does not terminate if the number is irrational. For instance

$$
\begin{aligned}
& (1+\sqrt{ } 5) / 2=[1,1,1,1, \ldots], \\
& e=[2,1,2,1,1,4,1,1,6,1,1,8,1,1, \ldots] .
\end{aligned}
$$

## RELATION WITH CONTINUED FRACTION EXPANSION

It was noted by Euler that the simple continued fraction of $\sqrt{ } \mathrm{D}$ is always periodic and is of the form
$\sqrt{D}=\left[a_{0}, \overline{a_{1}, \ldots, a_{h-1}, a_{h-1}, \ldots, a_{1}, 2 a_{0}}\right]$ if $k=2 h-1$,
$\sqrt{D}=\left[a_{0}, \overline{a_{1}, \ldots, a_{h-1}, a_{h}, a_{h-1}, \ldots, a_{1}, 2 a_{0}}\right]$ if $k=2 h$,
where $k$ is the length of the period, and the convergents $\mathrm{A}_{\mathrm{k}-1}, \mathrm{~B}_{\mathrm{k}-1}$ satisfy

$$
\mathrm{A}_{\mathrm{k}-1}^{2}-\mathrm{DB}_{\mathrm{k}-1}^{2}=(-1)^{\mathrm{k}}
$$

Further, all the solutions of, $\mathrm{X}^{2}-\mathrm{D} \mathrm{Y}^{2}=1$ can be obtained by composing (bhāvanā) of the above solution with itself.

These results were later proved by Lagrange.
Example: To solve $\mathrm{X}^{2}-13 \mathrm{Y}^{2}=1$

$$
\sqrt{13}=3+\overline{\frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{6+}}
$$

$\mathrm{A}_{4} / \mathrm{B}_{4}=18 / 5$ and we have $18^{2}-13.5^{2}=-1$, leading to $649^{2}-13.180^{2}=1$

## BHĀSKARA SEMI-REGULAR CONTINUED FRACTIONS

In a couple of papers which appeared during 1938-41, Krishnaswami Ayyangar showed that the cakravāla procedure actually corresponds to a "semi-regular continued fraction" expansion of $\sqrt{ }$ D.

A semi-regular continued fraction is of the form

$$
a_{0}+\varepsilon_{1} / a_{1+} \varepsilon_{2} / a_{2+} \varepsilon_{3} / a_{3+} .
$$

where $\varepsilon_{\mathrm{i}}= \pm 1, a_{\mathrm{i}} \geq 1$ for $i \geq 1$, and $a_{\mathrm{i}}+\varepsilon_{\mathrm{i}+1} \geq 1$ for $i \geq 1$.
Then the convergents satisfy the relations

$$
\begin{aligned}
& \mathrm{A}_{0}=a_{0}, \mathrm{~A}_{1}=a_{1} a_{0}+\varepsilon_{1}, \\
& \mathrm{~A}_{\mathrm{j}}=a_{\mathrm{j}} \mathrm{~A}_{\mathrm{j}-1}+\varepsilon_{\mathrm{j}} \mathrm{~A}_{\mathrm{j}-2} \text { for } j \geq 2 \\
& \mathrm{~B}_{0}=1, \mathrm{~B}_{1}=a_{1}, \\
& \mathrm{~B}_{\mathrm{j}}=a_{\mathrm{j}} \mathrm{~B}_{\mathrm{j}-1}+\varepsilon_{\mathrm{j}} \mathrm{~B}_{\mathrm{j}-2} \text { for } j \geq 2
\end{aligned}
$$

## BHĀSKARA SEMI-REGULAR CONTINUED FRACTIONS

Krishnaswami Ayyangar showed that the cakravāla method of Bhāskara corresponds to a periodic semi-regular continued function (Nearest Square Continued Fraction) expansion

$$
\sqrt{ } \mathrm{D}=a_{0}+\varepsilon_{1} / a_{1+} \varepsilon_{2} / a_{2+} \varepsilon_{3} / a_{3+} \ldots
$$

where $a_{i}=\left(\mathbf{P}_{\mathbf{i}}+\mathbf{P}_{\mathrm{i}+1}\right) /\left|\mathbf{K}_{\mathrm{i}}\right|, \boldsymbol{\varepsilon}_{\mathrm{i}}=\left(\mathbf{D}-\mathbf{P}_{\mathrm{i}}{ }^{2}\right) /\left|\mathbf{D}-\mathbf{P}_{\mathrm{i}}{ }^{2}\right|$ and the convergents are related to the solutions $\mathbf{A}_{\mathbf{j}}=\mathbf{X}_{\mathbf{j}+1}$ and $\mathbf{B}_{\mathbf{j}}=\mathbf{Y}_{\mathbf{j}+1}$.

Note: The Simple Continued Fraction of Euler-Lagrange and the Nearest Integer Continued Fraction can also be generated by a cakravāla type of algorithm if we replace the condition II respectively by
(II') D - $\mathbf{P}_{\mathrm{i}+1}{ }^{2}>0$ and is minimum
(II'') $\left|\mathbf{P}_{\mathrm{i}+1}-\mathrm{VD}\right|$ is minimum
[The Nearest Integer Continued Fraction expansion is implicit in the variant of the cakravāla method discussed by Nārāyaṇa Paṇdita in his Ganitakaumudī (c.1356). It was discovered as a more optimal method for solving "Pell's equation" than SCF by B. Minnigerode in 1873]

## EULER-LAGRANGE METHOD FOR X ${ }^{2}-67 \mathrm{Y}^{2}=1$

| $\mathbf{I}$ | $\mathbf{P}_{\mathbf{i}}$ | $\mathbf{K}_{\mathbf{i}}$ | $\mathbf{a}_{\mathbf{i}}$ | $\boldsymbol{\varepsilon}_{\mathbf{i}}$ | $\mathbf{X}_{\mathbf{i}}$ | $\mathbf{Y}_{\mathbf{i}}$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0 | 1 | 8 | 1 | 1 | 0 |
| 1 | 8 | -3 | 5 | 1 | 8 | 1 |
| 2 | 7 | 6 | 2 | 1 | 41 | 5 |
| 3 | 5 | -7 | 1 | 1 | 90 | 11 |
| $\mathbf{4}$ | $\mathbf{2}$ | $\mathbf{9}$ | $\mathbf{1}$ | $\mathbf{1}$ | $\mathbf{1 3 1}$ | $\mathbf{1 6}$ |
| 5 | 7 | -2 | 7 | 1 | 221 | 27 |

| 8 | 5 | 4 | 3 | 1 | 1523 | 195 |
| 9 | 7 | -3 | 4 | 1 | 5639 | 722 |
| $\mathbf{1 0}$ | 5 | 12 | 1 | 1 | $\mathbf{2 4 0 7 9}$ | $\mathbf{3 0 8 3}$ |
| 11 | 7 | -1 | 14 | 1 | 29718 | 3805 |

The steps which are skipped in cakravāla are highlighted

## EULER-LAGRANGE METHOD FOR $\mathrm{X}^{2}-61 \mathrm{Y}^{2}=1$ (CONTD)

| $\mathbf{1 2}$ | 7 | 12 | 1 | 1 | $\mathbf{4 4 0 1 3 1}$ | $\mathbf{5 6 3 5 3}$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 13 | 5 | -3 | 4 | 1 | 469849 | 60158 |
| 14 | 7 | 4 | 3 | 1 | 2319527 | 296985 |
| $\mathbf{1 5}$ | 5 | -9 | 1 | 1 | $\mathbf{7 4 2 8 4 3 0}$ | $\mathbf{9 5 1 1 1 3}$ |
| 16 | 4 | 5 | 2 | 1 | 9747967 | 1248098 |
| 17 | 6 | -5 | 2 | 1 | 26924344 | 3447309 |
| $\mathbf{1 8}$ | 4 | 9 | 1 | 1 | $\mathbf{6 3 5 9 6 6 4 5}$ | $\mathbf{8 1 4 2 7 1 6}$ |
| 19 | 5 | -4 | 3 | 1 | 90520989 | 11590025 |
| 20 | 7 | 3 | 4 | 1 | 335159612 | 42912791 |
| $\mathbf{2 1}$ | 5 | -12 | 1 | 1 | $\mathbf{1 4 3 1 1 5 9 4 3 7}$ | $\mathbf{1 8 3 2 4 1 1 8 9}$ |
| 22 | 7 | 1 | 14 | 1 | 1766319049 | 226153980 |

The corresponding simple continued fraction expansion is

$$
\sqrt{6} 1=7+\frac{1}{1+} \frac{1}{4+} \frac{1}{3+} \frac{1}{1+} \frac{1}{2+} \frac{1}{2+} \frac{1}{1+} \frac{1}{3+} \frac{1}{4+} \frac{1}{1+} \frac{1}{14+}
$$

The Bhāskara nearest square continued fraction is given by
$\sqrt{6} 1=8+\frac{-1}{5+} \frac{1}{4+} \frac{-1}{3+} \frac{1}{3+} \frac{-1}{4+} \frac{1}{5+} \frac{-1}{16+}$

## BHĀSKARA OR NEAREST SQUARE CONTINUED FRACTION

In the continued fraction development of $\sqrt{ } \mathrm{D}$, the complete quotients are quadratic surds which may be expressed in the standard form $(P+\sqrt{ }) / Q$, where $\mathrm{P}, \mathrm{Q}$ and $\left(\mathrm{D}-\mathrm{P}^{2}\right) / \mathrm{Q}$ are integers prime to each other.

If $a=[(P+\sqrt{ } D) / Q]$ is the integral part of $(P+\sqrt{ } D) / Q$, then we can have

$$
\begin{align*}
& (\mathrm{P}+\sqrt{ } \mathrm{D}) / \mathrm{Q}=a+\mathrm{Q}^{\prime} /\left(\mathrm{P}^{\prime}+\sqrt{ } \mathrm{D}\right)  \tag{I}\\
& (\mathrm{P}+\sqrt{ } \mathrm{D}) / \mathrm{Q}=(a+1)-\mathrm{Q}^{\prime \prime} /\left(\mathrm{P}^{\prime \prime}+\sqrt{ } \mathrm{D}\right) \tag{II}
\end{align*}
$$

where the surds in the rhs are also in the standard form.
In the Bhāskara or Nearest Square Continued Fraction development we choose $a$ as the partial quotient
(i) if $\left|\mathrm{P}^{12}-\mathrm{D}\right|<\left|\mathrm{P}^{122}-\mathrm{D}\right|$,
ii) or if $\left|\mathrm{P}^{\prime 2}-\mathrm{D}\right|=\left|\mathrm{P}^{\prime \prime 2}-\mathrm{D}\right|$ and $\mathrm{Q}<0$. Then we set $\varepsilon=1$.

Otherwise we choose $a+1$ as the partial quotient and $\operatorname{set} \varepsilon=-1$.
Note: If we start with $\sqrt{ } D$, we always have $P_{i} \geq 0$ and $Q_{i}>0$ and

$$
\mathrm{K}_{\mathrm{i}}=(-1)^{\mathrm{i}} \varepsilon_{1} \varepsilon_{2} \ldots \varepsilon_{\mathrm{i}} \mathrm{Q}_{\mathrm{i}}
$$

## BHĀSKARA OR NEAREST SQUARE CONTINUED FRACTION

Krishnaswami Ayyangar showed that the Bhāskara or nearest square continued fraction of $\sqrt{ } \mathrm{D}$ is of the form

$$
\sqrt{D}=a_{0}+\sqrt{\frac{\varepsilon_{1}}{a_{1}+} \frac{\varepsilon_{2}}{a_{2}+} \frac{\varepsilon_{3}}{a_{3}+} \ldots \frac{\varepsilon_{k-1}}{a_{k-1}+} \frac{\varepsilon_{k}}{2 a_{0}+}}
$$

where $k$ is the period. Further, it has the following symmetry properties:
Type I: There is no complete quotient of the form $\left[p+q+\sqrt{ }\left(p^{2}+q^{2}\right)\right] / p$, where $p>2 q>0$ are mutually prime integers. In this case, the Bhāskara continued fraction for $\sqrt{ } \mathrm{D}$ has same symmetry properties as in the case of Simple Continued Fraction expansion.

$$
\begin{array}{ll}
a_{v}=a_{k-v}, & 1 \leq v \leq k-1, \\
Q_{v}=Q_{k-v}, & 1 \leq v \leq k-1, \\
\epsilon_{v}=\epsilon_{k+1-v}, & 1 \leq v \leq k, \\
P_{v}=P_{k+1-v}, & 1 \leq v \leq k .
\end{array}
$$

## BHĀSKARA OR NEAREST SQUARE CONTINUED FRACTION

Examples of Type I:
$\sqrt{61}=8+\overline{\frac{-1}{5+} \frac{1}{4+} \frac{-1}{3+} \frac{1}{3+} \frac{-1}{4+} \frac{1}{5+} \frac{-1}{16+}}$
$\sqrt{6} 7=8+\frac{1}{5+} \frac{1}{2+} \frac{1}{2+} \frac{-1}{9+} \frac{-1}{2+} \frac{1}{2+} \frac{1}{5+} \frac{1}{16+}$
Type II: There is a complete quotient of the form $\left.\left[p+q+\sqrt{( } p^{2}+q^{2}\right)\right] / p$, where $\mathrm{p}>2 \mathrm{q}>0$ are mutually prime integers. In such a case, the period $k \geq 4$ and is even and there only one such complete quotient which occurs at $k / 2$. The symmetry properties are same as for Type I, except that

$$
a_{\frac{k}{2}}=2, \epsilon_{\frac{k}{2}}=-1, \epsilon_{\frac{k}{2}+1}=1, a_{\frac{k}{2}-1}=a_{\frac{k}{2}+1}+1, P_{\frac{k}{2}} \neq P_{\frac{k}{2}+1}
$$

Examples of Type II:

$$
\begin{aligned}
& \sqrt{5} 8=8+\frac{-1}{3+\frac{-1}{2+} \frac{1}{2+} \frac{-1}{16+}} \\
& \sqrt{97}=10+\frac{-1}{7+} \frac{-1}{3+} \frac{-1}{2+} \frac{1}{2+} \frac{-1}{7+} \frac{-1}{20+}
\end{aligned}
$$

## LEHMER ON BHĀSKARA CONTINUED FRACTION

The American number theorist Derrick Henry Lehmer (1905-1991) reviewed the work of Krishnaswami Ayyangar in the Mathematical Reviews (1944):
"These papers are concerned with a peculiar semi-regular continued fraction algorithm somewhat akin to the nearest integer algorithm. The expansion is defined only for the standard quadratic surd... and is presumably based on Bhāskara's 'cyclic method' of solving the Pell equation, although the author does not trace the connection in detail...

The author proves that the period is either symmetric, as in the regular case, or else 'almost symmetric', that is symmetric except for three central asymmetric partial quotients...

The theory of this continued fraction in most respects closely parallels the classical regular case of Lagrange. The slight blemishes characteristic of the new (or should one say $12^{\text {th }}$ century) algorithm do not seem to be compensated by any useful features other than that possessed by the nearest integer algorithm...."

## RECENT WORK ON "PELL’S EQUATION"

"Pell's equation" continues to be an important subject of current research.
The period $k(\mathrm{D})$ of the simple continued fraction expansion of $\sqrt{ } \mathrm{D}$ is a good measure of the number of steps needed to solve the equation. And this is known to fluctuate wildly between as low a value as 1 and an upper bound which is of the order of $(\sqrt{ } \mathrm{D}) \log (\mathrm{D})$. The solutions are similarly bounded above by a multiple of $D \exp (\sqrt{ } \mathrm{D})$

For instance, for $\mathrm{D}=1620, k(\mathrm{D})=1$ and we have the roots $(161,4)$
For $\mathrm{D}=1621, k(\mathrm{D})=78$ (the NSCF has a period of 56), and the larger root has 76 digits!

While it is true that even writing down the solutions involves exponential time (in terms of input length $\log \mathrm{D}$ ), various algebraic number theoretic techniques are being developed to obtain a significant number of digits of the solution by "faster" means. Recently Hallgren (2002) has come up with a polynomial-time quantum algorithm for the same purpose.

## MID-POINT CRITERIA

Recently, Mathews, Robertson and White (2010) have worked out the mid-point criteria for the Bhāskara continued fraction expansion of $\sqrt{ } D$.

In the case of the Simple Continued Fraction expansion of $\sqrt{ } \mathrm{D}$, the midpoint criteria were given by Euler:

If $\mathrm{Q}_{\mathrm{h}-1}=\mathrm{Q}_{\mathrm{h}}\left(\right.$ or $\left.\left|\mathrm{K}_{\mathrm{h}-1}\right|=\left|\mathrm{K}_{\mathrm{h}}\right|\right)$, then the period $k=2 h-1$ and

$$
\begin{aligned}
& \mathrm{A}_{\mathrm{k}-1}=\mathrm{A}_{\mathrm{h}-1} \mathrm{~B}_{\mathrm{h}-1}+\mathrm{A}_{\mathrm{h}-2} \mathrm{~B}_{\mathrm{h}-2} \\
& \mathrm{~B}_{\mathrm{k}-1}=\mathrm{B}_{\mathrm{h}-1}{ }^{2}+\mathrm{B}_{\mathrm{h}-2^{2}}
\end{aligned}
$$

which satisfy $A_{k-1}{ }^{2}-\mathrm{DB}_{\mathrm{k}-1}{ }^{2}=-1$

If $\mathrm{P}_{\mathrm{h}}=\mathrm{P}_{\mathrm{h}+1}$, then the period $k=2 h$ and

$$
\begin{aligned}
& A_{k-1}=A_{h-1} B_{h}+A_{h-2} B_{h-1} \\
& B_{k-1}=B_{h-1}\left(B_{h}+B_{h-2}\right)
\end{aligned}
$$

which satisfy $\mathrm{A}_{\mathrm{k}-1}{ }^{2}-\mathrm{DB}_{\mathrm{k}-1}{ }^{2}=1$

## MID-POINT CRITERIA

Mathews et al have obtained the following mid-point criteria for the Bhāskara or the Nearest Square Continued Fraction expansion of $\sqrt{ } \mathrm{D}$ :

If $\mathrm{Q}_{\mathrm{h}-1}=\mathrm{Q}_{\mathrm{h}}$ (or $\left|\mathrm{K}_{\mathrm{h}-1}\right|=\left|\mathrm{K}_{\mathrm{h}}\right|$ ), then the period $k=2 h-1$ and

$$
\begin{aligned}
& \mathrm{A}_{\mathrm{k}-1}=\mathrm{A}_{\mathrm{h}-1} \mathrm{~B}_{\mathrm{h}-1}+\varepsilon_{\mathrm{h}} \mathrm{~A}_{\mathrm{h}-2} \mathrm{~B}_{\mathrm{h}-2} \\
& \mathrm{~B}_{\mathrm{k}-1}=\mathrm{B}_{\mathrm{h}-1}{ }^{2}+\varepsilon_{\mathrm{h}} \mathrm{~B}_{\mathrm{h}-2}^{2}
\end{aligned}
$$

which satisfy $\mathrm{A}_{\mathrm{k}-1}{ }^{2}-\mathrm{DB}_{\mathrm{k}-1}{ }^{2}=-\varepsilon_{\mathrm{h}}$

If $\mathrm{P}_{\mathrm{h}}=\mathrm{P}_{\mathrm{h}+1}$, then the period $k=2 h$ and

$$
\begin{aligned}
& \mathrm{A}_{\mathrm{k}-1}=\mathrm{A}_{\mathrm{h}-1} \mathrm{~B}_{\mathrm{h}}+\varepsilon_{\mathrm{h}} \mathrm{~A}_{\mathrm{h}-2} \mathrm{~B}_{\mathrm{h}-1} \\
& \mathrm{~B}_{\mathrm{k}-1}=\mathrm{B}_{\mathrm{h}-1}\left(\mathrm{~B}_{\mathrm{h}}+\varepsilon_{\mathrm{h}} \mathrm{~B}_{\mathrm{h}-2}\right)
\end{aligned}
$$

which satisfy $\mathrm{A}_{\mathrm{k}-1}{ }^{2}-\mathrm{DB}_{\mathrm{k}-1}{ }^{2}=1$
In the Type I case, the mid-point will in variably satisfy one of the above two criteria.

## MID-POINT CRITERIA

In the Type II case, the following is the mid-point criterion:
When $\mathrm{Q}_{\mathrm{h}}=\left|\mathrm{K}_{\mathrm{h}}\right|$ is even and $\mathrm{P}_{\mathrm{h}}=\mathrm{Q}_{\mathrm{h}}+(1 / 2) \mathrm{Q}_{\mathrm{h}-1}=\left|\mathrm{K}_{\mathrm{h}}\right|+(1 / 2)\left|\mathrm{K}_{\mathrm{h}-1}\right|$ and $\varepsilon_{\mathrm{h}}=1$, then $k=2 h$ and

$$
\begin{aligned}
& A_{k-1}=A_{h} B_{h-1}-B_{h-2}\left(A_{h-1}-A_{h-2}\right) \\
& B_{k-1}=2 B_{h-1}^{2}-B_{h} B_{h-2}
\end{aligned}
$$

which satisfy $\mathrm{A}_{\mathrm{k}-1}{ }^{2}-\mathrm{DB}_{\mathrm{k}-1}{ }^{2}=1$
These mid-point criteria serve to further simplify the computation of the solution.

Note: The mid-point criteria for the Nearest Integer Continued Fraction expansion, obtained by Williams and Buhr (1979), are considerably more complicated than the above mid-point criteria for NSCF.

## OPTIMALITY OF CAKRAVĀLA METHOD

We have already remarked that the cakravāla process skips certain steps in the Euler-Lagrange process. Sometimes the period of Euler-Lagrange continued fraction expansion could be double (or almost double) the period of Bhāskara expansion. For instance, for $\mathrm{D}=13,44,58$, we have the following:

BCF: $\sqrt{13}=4+\overline{\frac{-1}{2+} \frac{1}{2+} \frac{-1}{8+}}$
SCF: $\sqrt{13}=3+\frac{1}{1+\frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{6+}}$
BCF: $\sqrt{4} 4=7+\frac{-1}{3+\frac{-1}{4+} \frac{-1}{3+} \frac{-1}{14+}}$
SCF: $\sqrt{44}=6+\frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{2+} \frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{12+}$
BCF: $\sqrt{5} 8=8+\overline{\frac{-1}{3+} \frac{-1}{2+} \frac{1}{2+} \frac{-1}{16+}}$
SCF: $\sqrt{5} 8=7+\frac{1}{1+\frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{1+} \frac{1}{14+}}$

## OPTIMALITY OF CAKRAVĀLA METHOD

We may note that whenever there is a 'unisequence' $(1,1, \ldots, 1)$ of partial quotients of length $n$, the cakravāla process skips exactly $(n / 2)$ steps if $n$ is even, and $(n+1) / 2$ steps if $n$ is odd.

In a series of papers (1960-63), Selenius has shown that the cakravāla process is 'ideal' in the sense that, whenever there is such a 'unisequence', only those convergents $A_{i} / B_{i}$ are retained for which $B_{i}\left|A_{i}-B_{i} \sqrt{ }\right|$ are minimal.

Recently, Mathews et al (2010) have shown that the period of Bhāskara or Nearest Square Continued Fraction is the same as that of the Nearest Integer Continued Fraction. They also estimate that the ratio of this period to that of simple continued fraction is $\log _{2}[(1+\sqrt{5}) / 2] \approx 0.6942419136 \ldots$

## OPTIMALITY OF CAKRAVĀLA METHOD

| $n$ | $\Pi(n)$ | $P(n)$ | $\Pi(n) / P(n)$ |
| :---: | :---: | :---: | :---: |
| $1,000,000$ | $152,198,657$ | $219,245,100$ | 0.6941941 |
| $2,000,000$ | $417,839,927$ | $601,858,071$ | 06942499 |
| $3,000,000$ | $755,029,499$ | $1,087,529,823$ | 0.6942609 |
| $4,000,000$ | $1,149,044,240$ | $1,655,081,352$ | 0.6942524 |
| $5,000,000$ | $1,592,110,649$ | $2,293,328,944$ | 0.6942356 |
| $6,000,000$ | $2,078,609,220$ | $2,994,112,273$ | 0.6942322 |
| $7,000,000$ | $2,604,125,007$ | $3,751,067,951$ | 0.6942356 |
| $8,000,000$ | $3,165,696,279$ | $4,559,939,520$ | 0.6944208 |
| $9,000,000$ | $3,760,639,205$ | $5,416,886,128$ | 0.6942437 |
| $10,000,000$ | $4,387,213,325$ | $6,319,390,242$ | 0.6942463 |

$\Pi(n)$ is the sum of the NSCF period lengths of $\sqrt{D}$ up to $n, D$ not a square, and $P(n)$ is the same for RCF.
