

Tutorial:

Cipher & Decipher

Sitabhra Sinha

IMSc, Chennai

A cipher is an algorithm – a series of well-defined steps that can be followed as a procedure – for performing encryption or decryption *Kryptós*, Gr. “hidden, secret”

Codes vs. Ciphers

- ❖ Codes generally substitute different length strings of characters in the output. A code maps Imageone meaning with another. Words and phrases can be coded as letters or numbers. operates by substituting using a codebook which links random strings of characters or numbers to a word or phrase. For example, “QQQQ” → “Get out of the auditorium fast”
- ❖ Ciphers generally substitute the same number of characters as are input. The given input must follow the cipher’s algorithmic process to be solved. The ciphertext message contains all the information of the plaintext message, but is not in a format readable by a human or computer without the proper mechanism to decrypt it.

Ché Guevara one-time pad cipher

Caesar cipher

A substitution cipher in which each letter in the plaintext is replaced by a letter some fixed number of positions down the alphabet.

Plaintext: THE QUICK BROWN FOX JUMPS OVER THE LAZY DOG

Ciphertext: QEB NRFZH YOLTK CLU GRJMP LSBO QEB IXWV ALD

One can also use another set of symbols to replace each letter of the alphabet

Frequency of English Characters

Samuel Morse
1791-1872

Telegraph

Highest frequency
characters

ETAOIN SHRDLU

To increase the efficiency of encoding, Morse code was originally designed so that the length of each symbol is approximately inverse to the frequency of occurrence of the character that it represents in text of the English language.

But Morse's character frequency counts are based on pieces of text considers the commonest words multiple times

Morse code

A	• —	U	• • —
B	— • • •	V	• • • —
C	— • — •	W	— • —
D	— • •	X	— • • —
E	•	Y	— • — —
F	• • — •	Z	— — • •
G	— — •		
H	• • • •		
I	• •		
J	• — — —		
K	— • —		
L	• — • •		
M	— —		
N	— •		
O	— — —		
P	• — — •		
Q	— — — •		
R	• — • •		
S	• • •		
T	—		
		1	• — — — —
		2	• • — — —
		3	• • • — —
		4	• • • • —
		5	• • • • •
		6	— • • • •
		7	— — • • •
		8	— — — • •
		9	— — — — •
		0	— — — — —

If one considers all distinct words so that word frequency does not produce artefacts, e.g., by considering words from a dictionary, the highest frequency characters are

EARIOT NSLCUD

In either case, E is the
commonest letter

Substitution ciphers in real life

A typical example of coded messages found in prisons in California sent to Stanford's Statistics Department for decryption

The image shows a handwritten coded message on lined paper. The message is written in a series of lines, using a combination of numbers, slashes, and dots to represent letters. The symbols are arranged in a way that suggests a substitution cipher. The message is written in a cursive, handwritten style, and the lines are somewhat irregular. The symbols used include numbers (0-9), slashes (/), and dots (.), often grouped together to form a single character or word. The message is written on a piece of lined paper, and the lines are clearly visible. The overall appearance is that of a handwritten note or a piece of evidence.

How to find the unknown function f such $f : \{\text{code space}\} \rightarrow \{\text{English alphabet}\}$

Markov chain Monte Carlo

A standard approach to deciphering is to use the statistics of written English to guess at probable choices for f , try these out, and see if the decrypted messages make sense.

The statistics is obtained from a text corpus. The proportion of consecutive text symbols from x to y gives a matrix $M(x; y)$ of 1st order transitions from one symbol to another. Then the plausibility of the mapping f

$$Pl(f) = \prod_i M(f(s_i), f(s_{i+1}))$$

where s_i runs over consecutive symbols in the coded message.

Mappings f which have high values of $Pl(f)$ are good candidates for deciphering. To maximize the plausibility we can run the following Markov Chain Monte Carlo algorithm

- Start with a preliminary guess, say f .
- Compute $Pl(f)$.
- Change to f_* by making a random transposition of the values f assigns to two symbols.
- Compute $Pl(f_*)$; if this is larger than $Pl(f)$, accept f_* .
- If not, flip a $Pl(f_*)/Pl(f)$ coin; if it comes up heads, accept f_* .
- If the coin toss comes up tails, stay at f .

“Reps do it”

The space of possible f s is extremely large – can the Monte Carlo guided random walk achieve the “correct” f in reasonable time, or at all?

ENTER HAMLET HAM TO BE OR NOT TO BE THAT IS THE QUESTION WHETHER TIS

Substitution ciphers in real life

Decipherment of the typical example of coded messages found in prisons in California sent to Stanford's Statistics Department for decryption

to bat-rb. con todo mi respeto. i was sitting down playing chess with danny de emf and boxer de el centro was sitting next to us. boxer was making loud and loud voices so i tell him por favor can you kick back homie cause im playing chess a minute later the vato starts back up again so this time i tell him con respecto homie can you kick back. the vato stop for a minute and he starts up again so i tell him check this out shut the f**k up cause im tired of your voice and if you got a problem with it we can go to celda and handle it. i really felt disrespected thats why i told him. anyways after i tell him that the next thing I know that vato slashes me and leaves. dy the time i figure im hit i try to get away but the c.o. is walking in my direction and he gets me right dy a celda. so i go to the hole. when im in the hole my home boys hit doxer so now "b" is also in the hole. while im in the hole im getting schoold wrong and

The Voynich Manuscript (c.15th century ?)

an illustrated codex, hand-written in an unknown script – language unknown

Image: Beinecke Rare Book & Manuscript Library

The vellum has been carbon-dated to 15th century
named after Wilfrid Voynich, a Polish book dealer who acquired it in 1912

Hypotheses range from a script for a natural language or constructed language, an unread code, cypher, or other form of cryptography, or perhaps a hoax!
